

Tudors' you'll have to play 2 games. Either Byzantium vs. Ottomans (As a part of the series games, a second player will play the same game with a different player controlling the Turks) or Venice vs. Venetians. A: Sorry but this is not possible. Even with 2 players, this would be ludicrous. At best this would be similar to a spectator mode where you can see the moves, but only see the 3D model of the units and not their abilities. The invention concerns a structural composite with at least one coated article. The invention further concerns a coated article comprising a structural composite of the above-mentioned type and its use in optical applications, in particular for imaging optical systems. The invention further concerns an optical system with a composite of the above-mentioned type. One of the most difficult tasks in building optical systems is to protect the optical components from mechanical stress. A considerable amount of work is done to meet these requirements by means of appropriate mechanical systems such as bellows, sliding panels or the like. However, such systems are subject to abrasion and are expensive, time-consuming and complicated to handle. For these reasons, composite materials are used, where the optical components are arranged in an intermediate layer. A conventional composite is composed of a support and an optical coating, which is in turn composed of two sub-layers. In this way the optical coating is protected from mechanical stress by the support. Such a composite can be produced by mixing materials (for example by casting or pressing) or by polymerizing monomers or oligomers and then carrying out a further process (for example curing or heat treatment). EP 1 011 121 A1 discloses an optical composite in which an optical coating is deposited on a substrate. To this end, a reactive monomer or oligomer, for example a reactive acrylate or a reactive epoxy, is applied to the substrate, after which it is polymerized in situ. The polymer is applied in an optionally pre-determined thickness to the substrate and then the optical coating, which is pre-disposed in the reactive monomer or oligomer, is cured by means of UV irradiation. In this way a composite is produced in which the optical coating is held by a substrate. One of the advantages of such composite materials is that they can be processed by means of the customary and simple production processes, for example pouring, casting or pressing, and, 82157476af
